

MEDICAL POLICY

Medical Policy Title	Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)
Policy Number	7.01.104
Current Effective Date	October 16, 2025
Next Review Date	October 2026

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to [Product Disclaimer](#))

POLICY STATEMENT(S)

- I. Minimally invasive treatment for benign prostatic hyperplasia (BPH) is **medically appropriate** when **ALL** of the following criteria are met:
 - A. Symptomatic benign prostatic hyperplasia (BPH);
 - B. As an alternative to Transurethral Resection of the Prostate (TURP) when **EITHER** of the following are met:
 1. Non-surgical methods have been tried (e.g., alpha blocker, PDE5 Inhibitor, finasteride/dutasteride) for at least three (3) months; **or**
 2. The patient is unable to tolerate non-surgical treatments;
 - C. With **ANY** of the following minimally invasive BPH treatments when associated criteria are met:
 1. Prostatic Urethral Lift (PUL) (i.e., UroLift)
 - a. Prostate volume 30-80cc;
 - b. Absence of **ANY** of the following contraindications;
 - i. Obstructive middle lobe verified by cystoscopy;
 - ii. Urethral conditions that may prevent insertion of delivery system into the bladder;
 - iii. Signs and symptoms of a urinary tract infection;
 - iv. Urinary incontinence due to incompetent sphincter; **or**
 - v. Current gross hematuria;
 2. Transurethral Water Vapor Thermal Therapy II (i.e., Rezūm)
 - a. 50 years of age or older; **and**
 - b. Prostate volume between 30-80cc;
 3. Waterjet Ablation Therapy (Aquabeam)
 - a. 45-80 years old; **and**

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 2 of 21

- b. Prostate volume 30-150cc; **or**
- 4. Prostate Artery Embolization (PAE)
 - a. Contraindication to general anesthesia must be well documented; **or**
 - b. Gross hematuria from the prostate; **and**
 - c. Performed by an interventional radiologist trained in this procedure.
- II. The following BPH treatments are considered **investigational**, including but not limited to:
 - A. Transperineal Laser Ablation (TPLA);
 - B. Temporary Implantable Nitinol Device (iTIND);
 - C. Drug coated balloons (e.g. Optilume).

POLICY GUIDELINE(S)

- I. The number of prostatic urethral lift implants will vary due to the unique characteristics of the prostate and prostatic urethra, but clinical data support an average of four (4) to five (5) implants per procedure.
- II. PUL devices do contain nickel, patients that have a known allergy to nickel should have a discussion with their provider before consenting to the procedure.

DESCRIPTION

Benign prostatic hyperplasia (BPH) is one of the most common afflictions in the aging man. It is a histologic diagnosis defined as the proliferation of smooth muscle and epithelial cells within the transition zone of the prostate gland. The enlarged gland has been proposed to contribute to the overall lower urinary tract symptoms (LUTS) complex through direct bladder outlet obstruction (BOO) from enlarged tissue and from increased smooth muscle tone and resistance within the enlarged gland. Voiding symptoms have often been attributed to the physical presence of BOO. BPH does not necessarily require treatment. The decision to treat is based on an assessment of the impact of the symptoms on quality of life, which can be significant. Patients with persistent symptoms despite medical management may be considered for surgical treatment. The traditional standard treatment is transurethral resection of the prostate (TURP).

Prostatic Urethral Lift (PUL) (e.g. UroLift System)

Prostatic urethral lift (PUL) system (e.g. UroLift System) is a minimally invasive, that provides anterolateral mechanical traction of the lateral lobes of the prostate, opening the urethral lumen and

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 3 of 21

reducing urinary obstruction. The delivery device contains a preloaded implant that deploys a permanent tensioning suture. The suture runs from the urethra to the outer prostatic capsule and serves to pull the lateral lobe of the prostate away from the urethra. Implants are delivered bilaterally to separate the encroaching lobes. Four to five implants are typically inserted, but this varies with the size and shape of the prostate. The UroLift System may be used to treat prostate glands measuring less than 80 milliliters (mL) and is implanted by a urologist in an outpatient or inpatient setting. The transurethral procedure to insert the UroLift is performed with the use of local or general anesthesia and oral sedation.

Transurethral Water Vapor Thermal Therapy (e.g. Rezūm System)

Transurethral water vapor thermal therapy has been investigated as a minimally invasive alternative to transurethral resection of the prostate. Transurethral water vapor thermal therapy is a transurethral needle ablation technique which injects radiofrequency-generated, sterile water vapor (~103 degrees C) into enlarged prostate tissue. As the steam encounters the prostatic tissue, it condenses back into water, releasing large amounts of thermal energy, disrupting the prostatic cell membranes, and leading to cell death and necrosis. It takes approximately three months for the body to reabsorb dead tissue, decreasing prostate volume and relieving LUTS. The thermal energy is confined to the prostate, which reduces the risk of injury to other parts of the body. The procedure is performed under local anesthesia in an office or outpatient setting.

Prostate Artery Embolization (PAE)

Prostate artery embolization (PAE) is a minimally invasive outpatient procedure that involves the release of microscopic, plastic beads into the arteries that feed the prostate gland. The beads travel to the patient's prostatic arteries, and once there, they permanently block off the blood flow that is causing the swelling in the prostate.

Transperineal Laser Ablation (TPLA)

Transperineal Laser Ablation (TPLA) is a minimally invasive procedure that involves use of a diode laser light which is passed through 300 μm optical fibers which are introduced transperineally and placed at a secure distance from urethra and bladder neck. EchoLaser Smart Interface assists easing needle positioning and increases safety. Several clinical trials are currently enrolling members for data collection.

Temporary Implantable Nitinol Device (iTIND)

Temporary implantable nitinol device (iTIND) is implanted cystoscopically and is designed to remodel the bladder neck and prostatic urethra through ischemic tissue necrosis and permanent mucosal incisions. iTIND was developed to be a truly minimally invasive, non-ablative therapy that does not carry the possible risks of leaving a permanent implant within the prostatic urethra. The iTIND device expands and exerts pressure on prostatic tissue, causing ischemic necrosis, the creation of compression channels, and a remodeling of the prostatic urethra and the bladder neck. This stent-like device is left in place for only five to seven days before being removed.

Transurethral Waterjet Ablation (e.g. Aquablation)

Transurethral Waterjet Ablation (Aquablation) uses a specialized system that combines image

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 4 of 21

guidance and robotics for the targeted heat-free removal of prostate tissue. The procedure is usually done with the patient under general or spinal anesthesia. Transrectal ultrasound is used throughout the procedure. A handpiece with an integrated cystoscope and ablation probe is inserted through the urethra and into the bladder. Positioning is confirmed by using visual markers on a computer screen, and the surgeon is able to plan the depth and angle of resection using the system software. Once the surgical mapping is complete, a high-speed jet of saline is delivered to the prostate at various flow rates, according to the depth of penetration needed. The ablated tissue is aspirated through ports in the handpiece and can be used for histological analysis.

Transurethral Balloon Dilatation (e.g. Optilume)

Transurethral balloon dilatation involves the insertion of a balloon catheter through the urethra into the prostatic urethra where it is inflated, theoretically pushing back prostate tissue and stretching the urethra where it has been narrowed by the prostate. An example of this includes but may not be limited to the Optilume Basic. The Optilume drug-coated balloon combines urethral dilation with circumferential topical delivery of paclitaxel.

SUPPORTIVE LITERATURE

Prostatic Urethral Lift

Roehrborn et al (2013) reported results of the L.I.F.T. (Luminal Improvement Following Prostatic Tissue Approximation for the Treatment of LUTS secondary to BPH) trial, which was the first multicenter, randomized, double-blinded trial of the prostatic urethral lift (PUL) for the treatment of LUTS secondary to BPH. Nineteen centers in three countries (United States, Canada, and Australia) enrolled 206 men, who were randomized 2:1 to treatment with either the PUL (n=140) or sham control (n=66) consisting of rigid cystoscopy. The primary endpoint was the reduction in AUASI at three months. Secondary measures included QOL, Benign Prostatic Hyperplasia Impact Index (BPHII), International Index of Erectile Function (IIEF), Male Sexual Health Questionnaire for Ejaculatory Dysfunction (MSHQ-EjD), Maximum urinary flow rate (Qmax), and PVR. Participants were followed for 12 months, with 123 PUL subjects included in the 12-month analysis. The primary endpoint was met with the PUL AUASI reduction 88% greater than sham control, 11.1 versus 5.9, respectively (p=0.003) and sustained at one year. Qmax increased 4.4 ml per second at three months and was sustained at 4.0 ml per second at 12 months, which was both clinically and statistically significant. Erectile function remained stable after the procedure. There were two serious adverse events, one clot retention and one bladder stone. Less serious adverse events (AE) (postoperative dysuria, hematuria, pain/discomfort, and urgency) were typically mild to moderate and resolved within two weeks. The authors concluded the prostatic urethral lift provides a clinically meaningful improvement in LUTS secondary to BPH and urinary flow and can be performed under local anesthesia with low morbidity and preservation of sexual function.

Sønksen et al (2015) conducted a randomized trial known as the BPH6 study, comparing PUL to TURP to determine LUTS improvement, recovery, worsening of erectile and ejaculatory function, continence, and safety. A total of 80 men across 10 European centers received either PUL (n=45) or TURP (n=35). One patient in the PUL group was excluded from analysis for violation of the active urinary retention exclusion criteria. At 12-month follow-up, the PUL group demonstrated an average

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 5 of 21

decrease of 11.4 in IPSS, while IPSS improvement after TURP was 15.4. PUL patients consistently had more rapid recovery than TURP patients (82% vs. 53% respectively). Significant improvements in IPSS, IPSS QoL, BPH II, and Qmax were observed in both groups over time. Erectile function was preserved in both PUL and TURP groups as measured by SHIM scores. The PUL group experienced an improvement in average ejaculatory score (MSHQEjD) from baseline ($p = 0.03$), but the TURP group suffered from a significant decline. For the BPH6 ejaculatory assessment, the response for the PUL group was 100%, significantly better than the 60.6% response for the TURP group ($p < 0.0001$). Continence preservation was comparable between the groups. The number of patients who experienced grade 2 and 3 adverse events was similar between groups. Of the participants who met the original BPH6 primary endpoint, 34.9% were in the PUL group and 8.6% were in the TURP group. Of the participants who met the modified BPH6 primary endpoint, 52.3% were in the PUL group and 20.0% were in the TURP group. Reintervention for failure to cure occurred in 6.8% (3/44) of PUL patients and 5.7% (2/35) of TURP patients (not significant). The authors concluded that both the PUL and TURP groups achieved significant symptom relief compared to baseline, with a superior symptom relief rate for TURP and a superior quality of recovery and preservation of ejaculatory function for PUL. Limitations include the short-medium follow-up, small sample size, and lack of blinding.

Roehrborn et al (2017) reported five-year results of the L.I.F.T. study. At five years of follow-up, data were available for 104 of 140 PUL subjects (74.3%). A total of 18 were lost to follow-up, nine died of unrelated causes; nine exited the study for other reasons. Surgical retreatment for failure to cure was 13.6%, with 4.3% receiving additional PUL implants and 9.3% undergoing TURP or laser ablation. The authors reported on two analyses, a per-protocol (PP) analysis and an intention-to-treat (ITT) analysis. A total of 72 patients were included in the PP analysis, after exclusions for protocol violations, additional BPH procedures, or treatment with BPH medication. Sustained improvements were reported based on the PP analysis in symptoms (36% IPSS), quality of life (50% QOL, 52% BPHII) and urinary flow rate (44% Qmax). No differences were seen between ITT and PP populations.

Gratzke et al (2017) reported two-year follow-up results from the BPH6 study. Over the two-year follow-up, six patients (13.6%) in the PUL group and two (5.7%) in the TURP group underwent secondary treatment for LUTS. Three additional patients discontinued study participation, resulting in 37 PUL patients and 32 TURP patients included in the two-year analysis. Significant improvements in International Prostate Symptom Score (IPSS), IPSS quality of life (QoL), BPH Impact Index (BPHII), and maximum urinary flow rate (Qmax) were observed in both groups throughout the two-year follow-up. Changes in IPSS and Qmax in the TURP group were superior to the PUL group. Improvements in IPSS QoL and BPHII score were not statistically different between the study groups. PUL resulted in superior quality of recovery, ejaculatory function preservation, and performance on the composite BPH6 index. Ejaculatory function bother scores did not change significantly in either treatment group. TURP significantly compromised continence function at two weeks and three months. Only PUL resulted in statistically significant improvement in sleep.

Rukstalis et al (2019) reported on the MedLift study, an U.S. Food and Drug Administration (FDA) IDE extension of the L.I.F.T. randomized study designed to examine safety and efficacy of PUL for treatment of obstructive middle lobes (OML). Compared to lateral lobe subjects from the historical

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 6 of 21

L.I.F.T. study, the 45 enrolled OML subjects' symptoms improved at least as much at every time point (OML range 13.5–15.9, LL range 9.9–11.1, $p=0.01$). The observed rate of post-procedure, device-related, serious complications was 0%, thereby achieving the primary safety composite endpoint. Published evidence, which includes the BPH6, L.I.F.T., and MedLift studies, support a clinically meaningful improvement in net health outcome.

Transurethral Water Vapor Thermal Therapy

McVary et al (2016) reported the results of a multi-center, randomized, controlled study (Rezum II study) using transurethral prostate convective water vapor thermal energy to treat LUTS associated with BPH. A total of 197 men aged 50 years and older were randomized 2:1 to thermal therapy, $n=136$, and control (insertion of a rigid cystoscope), $n=61$. The primary endpoint was an IPSS reduction at three months greater than 125% in the treatment group as compared to the control. Results showed IPSS was reduced by 50% compared with 20% reduction for control. Therapy outcomes for the treatment group, including Q_{max} , Q_{oL} ($p < 0.0001$) and BPHII ($p= 0.0003$), were significantly improved compared to control and sustained throughout 12 months. Two treatment subjects had three serious AEs adjudicated as procedure-related: extended urinary retention, nausea, and vomiting. The authors concluded that convective water vapor energy ablation of prostate adenomas provides statistically significant and clinically meaningful improvements within two weeks after treatment for LUTS due to BPH. Limitations of the study include the short follow-up period and small sample size.

McVary et al (2019) reported four-year outcomes of the randomized controlled trial of water vapor thermal therapy study. Out of the original 135 subjects who underwent water vapor therapy, 90 (66.7%) were included in the 48-month per protocol analysis. IPSS improvements from baseline remained consistent from the early response at three months (49.9%) to year 1 (52.2%), year 2 (50.7%), year 3 (49.7%), and year 4 (46.7%). Flowrate improvements were sustained relative to baseline, remaining significant, although an increase of 5.5 at one year to a mean 4.2 mL/s at four years was noted. Men with moderate and severe LUTS had symptomatic relief with similar IPSS improvements at four years of 46.1% and 46.9% and Q_{max} of 45% and 51.3%, respectively. QOL and BPH Impact Index remained improved at 43% and 52% respectively, $P < .0001$. Throughout the four years, urinary incontinence scores decreased significantly. Sexual function throughout two years after treatment shows that erectile function (IIEF) and ejaculatory function (MSHQ-EjD) scores remained unchanged but worsened at four years. At four years, surgical intervention was performed in six of 135 subjects (4.4%) including four subjects in whom a median lobe was identified but not treated. Comparatively, surgical retreatment rates for TUNA are 19.1% at three years and 14%-51% at five years. TUMT retreatment at five years is 8.9%-21%, and prostatic urethral lift procedure has a reported surgical retreatment of 10.6% at three years and 13.6% at five years. The authors concluded that water vapor thermal therapy provides effective symptom relief and improved QOL that remained durable throughout four years.

McVary et al (2021) reported his final five-year outcomes of the randomized controlled trial for water vapor thermal therapy for treatment of moderate to severe lower urinary tract symptoms secondary to benign prostatic hypertrophy (BPH). Significant improvement of lower urinary tract symptoms was observed at <3 months post-thermal therapy, remaining durable through 5 years in the treatment

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 7 of 21

group. At five years, the International Prostate Symptom Score reduced 48%, quality of life increased 45%, maximum flow rate improved 44%, and the Benign Prostatic Hyperplasia Impact Index decreased 48%. Surgical re-treatment rate was 4.4% with no reports of device or procedure related sexual dysfunction or sustained de novo erectile dysfunction.

In addition, the efficacy and safety of Rezum water vapor thermal therapy was further supported through a prospective pilot study, a crossover study, and two retrospective studies where outcomes demonstrated improvements in patients International Prostate Symptom Score (IPSS), quality of life (QoL), Qmax and post void residual (PVR) without causing deterioration of sexual function.

Evidence for transurethral water vapor thermal therapy mostly consists of one small, short-term, sham controlled RCT with a five-year uncontrolled follow-up phase. LUTS improved more in the intervention group (50%) compared to sham (20%) at three months. Improvements were sustained through four years of follow-up. No adverse events of erectile or ejaculatory function were observed with scores unchanged through two years of follow-up. Based on the single, short-term, sham-controlled study with a five-year uncontrolled follow-up phase, BPH treatment with water vapor thermal therapy resulted in improved health outcomes which remained stable throughout the five years.

Prostate Artery Embolization (PAE)

Bhatia et al (2025) conducted a retrospective study evaluated the mid- to long-term safety and effectiveness of prostatic artery embolization (PAE) in 1,075 patients treated at a single center between January 2014 and July 2023. Patients had moderate-to-severe lower urinary tract symptoms (LUTS) or urinary retention who had undergone PAE. They were followed for a mean of 458.4 days and assessed at 1, 3, 6, and 12 months after PAE and thereafter. Mean prostate volume (PV) was 107 grams, and the median preprocedural IPSS was 23, QoL was 5, and IIEF-5 score was 17 and PSA level was 4.7ng/ml. In the LUTS subgroup, at 1–3, 6–12, and 48–60 months, the median IPSS values were 7, 6, and 9, respectively. Of 126 patients in the retention cohort, 119 (94%) were catheter-free at the 3-month follow-up. Up to 60 months after PAE, 90 patients (16% of reintervention eligible patients) required a second prostatic intervention. After PAE, 65.5% of patients were BPO medication-free at 1 year. Adverse events were rare, in 7 patients and resolved without lasting effects, including prostate sloughing, urosepsis and transient ischemic attacks. Overall, PAE demonstrated durable symptom relief, improved quality of life, and a favorable safety profile with sustained relief up to 60 months.

Brown et al (2024) conducted a randomized controlled trial to assess PAE as a first line therapy compared to medication in treatment of naïve men with prostate enlargement known as the P-EASY ADVANCE trial. The trial consisted of 39 men with enlarged prostates, moderate-severe lower urinary tract symptoms and obstructed/equivocal urodynamic studies (UDS), and who had no prior treatment for BPH. They were randomized to receive either combined medical therapy or PAE. Follow-up was conducted by assessing UDS, International Prostate Symptom Score (IPSS), uroflowmetry and ultrasound at short- to medium-term intervals and compared to baseline. Both interventions improved voiding and bladder outflow obstruction from baseline (unobstructed after PAE 63%, medication 28%). PAE patients had greater reduction in prostate size, incomplete emptying, total IPSS, and quality of life. In the medication group, altered ejaculation, erectile

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 8 of 21

dysfunction and nausea were more common. Although PAE showed to be more effective than the combined medical therapy, authors state that “further randomized comparative trials are planned to validate the role of PAE in mitigating obstructive BPH.”

Müllhaupt et al (2024) conducted a randomized, open-label, single center trial of 103 patients with refractory LUTS/benign prostatic obstruction (BPO). They aimed to compare the safety and efficacy of PAE and TURP treatment at 5-year follow up. Primary outcome was the change in IPSS after PAE versus TURP. Secondary outcome included patient-reported outcomes, functional measures and adverse events. The outcomes were measured at 3, 6, 12, 24, and 60 months. Of the randomized patients with LUTS/BPO, 18/48 in the PAE group and 38/51 in the TURP group completed 5-year follow-up. Mean IPSS reduction was -7.78 for PAE and -11.57 for TURP (difference 3.79; 95% CI -0.66 to 8.24). TURP showed superior patient-reported outcomes except erectile function. At 5 years, TURP was more effective than PAE in improving urinary flow (9.30 vs 3.59 ml/s; difference -5.71) and reducing postvoid residual volume (219.97 vs 27.81 ml; difference 192.15). The study had notable limitations. Blinding of patients and physicians wasn't possible, and five patients per group were lost to follow-up. Additional dropouts left only 18 PAE and 38 TURP patients for analysis, reducing statistical power and preventing subgroup analysis. This likely contributed to the loss of significance in some comparisons at the 5-year follow-up. Furthermore, five of 20 patients who required TURP after unsatisfactory PAE outcomes could only undergo unilateral embolization, which may have impacted results. The authors state “the improvements in subjective and objective outcomes are more pronounced after TURP and thus PAE is not a definitive treatment in the long term for a relevant proportion of patients, especially those with advanced LUTS/BPO stage requiring maximum relief of bladder outlet obstruction.”

Marchi et al (2023) conducted a retrospective single-center with the primary objective to assess long-term outcomes of PAE in 88 patients with acute urinary retention related to BPH. Urinary catheter was attempted at two weeks post PAE, success was defined as the absence of acute urinary retention recurrence. In the month following catheter removal 82% of patients were successful and 16% had immediate recurrence. Clinical success persisted for 66% of patients at long term follow-up (mean follow-up: 19.5 months \pm 16.5 [SD]; range: 2–74 months). Recurrence occurred at a mean of 16.2 months \pm 12.2 (SD) (range: 1.5–43 months) post-PAE. Overall, 24% patients of the cohort underwent prostatic surgery, at a mean of 10.4 months \pm 12.2 (SD) (range: 1.2–42.4 months) from initial PAE. No correlations between patient variables or bilateral PAE and long-term clinical success were identified. Kaplan-Meier analysis showed a three-year catheter free probability of 60%. They state that further investigation is needed in patients with acute urinary retention (AUR) recurrence during long-term follow-up.

Carnevale et al (2020) conducted a retrospective single center study in 317 patients with moderate to severe BPH. Participants were followed for 96 months to evaluate the efficacy, and long-term results of PAE for BPH. Participants received PAE, 94% received bilateral and 6% received unilateral. Over a median follow-up of 72 months, early clinical failure occurred in 1.9%, and 23% experienced symptom recurrence significantly higher in the unilateral group (42% vs. 21%). Average improvements included a 16-point drop in IPSS, 4-point improvement in quality-of-life score, 39 cm³ reduction in prostate volume (39%), a 6 mL/sec increase in urinary flow (155%), and a 70 mL decrease in postvoid residual volume (48%), all statistically significant ($P < .05$). Higher baseline PSA

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 9 of 21

levels were linked to lower recurrence risk (HR 0.9; 95% CI: 0.8–0.9; $P < .001$). Embolization with mixed particle sizes (100–500 μm group vs 300–500 μm group) showed no significant impact on recurrence. No patients reported urinary incontinence or erectile dysfunction. Limitations included, that early PAE procedures lacked cone-beam CT, cone-beam CT has since enhanced pelvic anatomy visualization and reduced both procedure and radiation time. Baseline IPSS was missing for men with catheters. Over 10 years, varied techniques and embolic agents were used, limiting consistency. Few patients had over five years of follow-up. The authors state that “although long-term results for PAE are promising, further investigations regarding optimal technical aspects of the procedure and patient selection are still required” stating that the data indicates it is a safe and effective procedure and has the potential to become an alternative procedure for BPH.

Transperineal Laser Ablation (TPLA)

Bianco et al (2021) presented at the 2021 American Urological Association annual meeting, the six month and twelve-month results of a study called transperineal laser ablation for benign prostatic hyperplasia (BPH): Feasibility and safety. This study was a Phase I trial, trial, whose objective was to evaluate feasibility, safety as well as three-, six- and twelve-months outcomes for TPLA. Twenty subjects were enrolled in this study. All subjects had complete lower urinary tract evaluation with pressure flow studies, international prostate symptom scores (IPSS) and sexual health inventory for men (SHIM) scores and ultrasonographic prostate volume measurements. Renal function biomarkers as well as PSA were collected. The protocol called for 2–4 Echolaser4 (Elesta Els, Italy) TPLA applications in the prostate under ultrasound guidance aided by the ELS tracing system. Although functional outcomes are pending, a 4-point median improvement in IPSS scores was seen at thirty days.

Temporary Implantable Nitinol Device (iTIND)

Kadner et al (2020) reported on the results of a single-arm, multicenter, international, prospective study that was conducted at nine sites from December 2014 to December 2016 under clinical trial NCT02145208. 81 men with symptomatic BPH (IPSS ≥ 10 , peak urinary flow $< 12\text{ml/s}$ and prostate volume $< 75\text{ml}$) were enrolled in this study. Kadner, et al., notes that a wash-out period of one month for alpha-blockers and six months for 5-alpha reductase inhibitors (5-ARIs) was mandatory to avoid variable confusion. The procedure was performed under light sedation with device implanted and removed five to seven days later with topical sedation. A total of 51 men completed follow up after two years. Mean Qmax and PVR were $7.62 \pm 2.25\text{ ml/s}$ and $65.84 \pm 38.46\text{ ml}$ at baseline, and IPSS and QoL scores were 20.51 ± 4.58 and 3.96 ± 0.87 , respectively. Implantation procedures elicited average pain VAS scores of 3.2 ± 1.6 and were all technically successful with no intraoperative complications. Implants were retrieved 5.7 ± 0.9 days after deployment. All objective and subjective measures showed statistically significant improvements ($p < 0.0001$) from baseline levels at all assessment points. IPSS urinary symptoms were reduced by 12.00 ± 6.12 points at the end of the follow-up period. Quality of life scores reflected symptomatic relief, with patients reporting a mean reduction of 2.4 points from baseline. Maximum urinary flow rate (Qmax) rose to $16.00 \pm 7.43\text{ ml/s}$, an average increase of $8.38 \pm 7.93\text{ ml/s}$. No deterioration in PVR was observed by the end of the follow-up period. Results suggest, that iTind implantation for treatment of LUTS secondary to BPH is associated with minimal perioperative morbidity and provides

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 10 of 21

rapid symptomatic and functional outcomes that are durable through 24 months follow-up. The need for reoperation or de-novo-medication is very low, except in patients with median lobes, who so far cannot be recommended for treatment. In contrast to medical and surgical alternatives, there is an indication that treatment with iTind does not pose a risk to ejaculatory and sexual functions, but this finding must be supported with further studies. The European Association of Urology guidelines acknowledge the emerging role of this device, no specific recommendation is given, and its formal role is therefore yet to be defined.

Transurethral Waterjet Ablation (Aquablation)

Aquablation for treatment of BPH has been assessed in a single RCT, known as WATER (Waterjet Ablation Therapy for Endoscopic Resection of Prostate Tissue). WATER was a noninferiority trial comparing aquablation with TURP in 181 participants at 17 sites in 4 countries. Participants were men ages 45 to 80 years with moderate-to-severe LUTS, defined as an IPSS 10 score ≥ 12 , and prostate size between 30 and 80 cc. The primary efficacy endpoint was the difference between groups in the change in IPSS at 6 months, and the primary safety endpoint was the development of Clavien-Dindo persistent grade 1, or 2 or higher operative complications at 3 months. Primary endpoint results were reported by Gilling et al in 2018, 12-month results in Gilling et al (2019), and 3-year results in Gilling et al (2020). Additionally, a synthesis of the trial results up to 12 months was reported in a Cochrane systematic review conducted by Hwang et al (2019). On the primary efficacy outcome, aquablation was noninferior to TURP. At 6 months, mean IPSS decreased from baseline by 16.9 points for aquablation and 15.1 points for TURP (mean difference 1.8 points; $p < .0001$ for noninferiority and $p = .1347$ for superiority). The primary safety endpoint rate was lower in the aquablation group compared to the TURP group (26% versus 42%, $p = .0149$). The rate of grade two (2) and greater events was similar in the two groups (20% for aquablation and 23% for TURP; $p = .3038$).

Berjaoui et al (2024) conducted a study to compare the long-term outcomes of Aquablation for small-to-moderate prostates (30-80 mL) in the WATER clinical trial, with the outcomes for large prostates (80-150 mL) in the WATER II clinical trial at a 5-year follow-up. Participants that made it to the 5-year follow up were 60 subjects from WATER II and 58 participants from WATER, just under half did not make it to the 5-year mark. Patients completed IPSS and Incontinence Severity Index (ISI) questionnaires. Also measured was uroflowmetry, PVR measurements, and standard laboratory testing. These questionnaires were repeated at months 1, 3, 6, 12, 24, 36, 48, and 60 months. PSA was repeated at 6 months and annually thereafter. Results demonstrated improvement in from baseline to 60 months in IPSS: WATER (22.9 to 7.0) and WATER II (23.2 to 6.8), Q_{max} : WATER (9.4 to 17.3 cc/s) and WATER II (8.7 to 17.1 cc/s). At the 5-year follow-up, patients that were medication-free for BPH (WATER: 99% and WATER II: 94%) and free from surgical retreatment (WATER: 95%; WATER II: 97%).

Optilume

DeLong et al (2025) reported the 5-year study closeout results for the ROBUST I trial that evaluated the safety and efficacy of the Optilume drug-coated balloon (DCB) for men with short, recurrent bulbar urethral strictures. The trial consisted of 53 men with recurrent bulbar urethral strictures. The strictures were less than or equal to 2cm long and a lumen or greater than 12 French and have

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 11 of 21

undergone between 1 and 4 prior endoscopic procedures, who all received the Optilume DCB. The outcomes were measured by symptom questionnaires, maximum urinary flow rate, postvoid residual, and freedom from repeat intervention. Of the 53 men, 31 completed all follow-up requirements, 58% achieved functional success at 5 years. Average IPSS improved from a mean of 25.2 at baseline to 7.2 at 5 years. 71.7% of the patients were free from repeat interventions throughout the 5 years. Urinary flow rate improved from 5.0 mL/s at baseline to 19.9mL/s. The average post void residual was reduced from 141.4 mL to 59.5 mL at 5 years. There was no serious treatment related adverse events, including erectile dysfunction. For men that wish to avoid urethroplasty based on this study Optilume is a safe and effective treatment option for appropriately selected men with recurrent bulbar urethral stricture.

Kaplan et al (2024) reported the 2-year long-term follow up from the PINNACLE study, a prospective, multicenter, randomized study that was evaluating the safety and effectiveness of the Optilume BPH catheter system. The study consisted of 148 men with symptomatic BPH, who were randomized in a 2:1 fashion to Optilume or a Sham. Success was measured by IPSS, peak urinary flow rate (Q_{max}), post void residual (PVR) urine, quality of life and sexual function, follow-up beyond 1 year was limited to those treated with the Optilume product. At 2 years 67.5% of participants treated with Optilume were considered symptomatic responders. Symptomatic responders are defined by $\geq 30\%$ improvement in IPSS without medical or surgical retreatment. IPSS improved from 23.4 to 11.0, Q_{max} improved by 116.8% to 19%, PVR had a reduction (83.7 ± 70.3 (n = 99) to 65.9 ± 74.5 (n = 65)).

Kaplan et al (2024) reported the 4-year results of the prospective single arm, open-label, multicenter EVEREST clinical study. The study aimed to gather initial safety and efficacy data of the Optilume BPH Catheter System for the treatment of lower urinary tract symptoms (LUTS) secondary to BPH. The study consisted of 80 men with moderate-to-severe LUTS secondary to BPH who were treated with Optilume. Symptoms were assessed using IPSS, BPH Impact Index, Q_{max} and PVR. Previously reported symptom improvements were maintained through 4-year follow-up, which included reduction in IPSS and IPSS quality of life. Q_{max} was maintained in majority of men, with an average improvement from baseline and no adverse events were reported. Some limitations of the study include the lack of a control group and small number of participants.

PROFESSIONAL GUIDELINE(S)

The American Urological Association (AUA) guidelines for Management of Lower Urinary Tract Symptoms Attributed to BPH (Lerner et al., 2023) state:

- TURP should be offered as a treatment option for patients with LUTS/BPH. (Moderate Recommendation; Evidence Level: Grade B)
- Transurethral incision of the prostate (TUIP) should be offered as an option for patients with prostates $\leq 30\text{g}$ for the surgical treatment of LUTS/BPH. (Moderate Recommendation; Evidence Level: Grade B)
- PVP should be offered as an option using 120W or 180W platforms for the treatment of LUTS/BPH. (Moderate Recommendation; Evidence Level: Grade B)

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 12 of 21

- PUL should be considered as a treatment option for patients with LUTS/BPH provided prostate volume 30-80g and verified absence of an obstructive middle lobe. (Moderate Recommendation; Evidence Level: Grade C)
- PUL may be offered as a treatment option to eligible patients who desire preservation of erectile and ejaculatory function. (Conditional Recommendation; Evidence Level: Grade C)
- Water Vapor Thermal Therapy (WVTT) should be considered as a treatment option for patients with LUTS/BPH provided prostate volume 30-80g. (Moderate Recommendation; Evidence Level: Grade C)
- WVTT may be offered as a treatment option to eligible patients who desire preservation of erectile and ejaculatory function. (Conditional Recommendation; Evidence Level: Grade C)
- Robotic waterjet treatment (RWT) may be offered as a treatment option to patients with LUTS/BPH provided prostate volume 30-80g. (Conditional Recommendation; Evidence Level: Grade C)
- PAE may be offered for the treatment of LUTS/BPH. PAE should be performed by clinicians trained in this interventional radiology procedure following a discussion of the potential risks and benefits. (Conditional Recommendation: Evidence level: Grade C)

The National Institute for Health and care Excellence (NICE) 2021 guidelines for Transurethral water jet ablation for LUTS/BPH states that evidence on transurethral water jet ablation for lower urinary tract symptoms caused by benign prostatic hyperplasia raises no major safety concerns. The evidence on efficacy is limited in quality. Therefore, this procedure should only be used with special arrangements for clinical governance, consent and audit or research.

The Society of Interventional Radiology in 2020 set out to develop a research agenda on PAE, recognizing that there is a need for well-designed trials. The goal was to discuss weaknesses with current data and study design in order to develop trials in the United States that would report long-term outcome data. The final consensus on a research design could not, therefore future meetings are required

REGULATORY STATUS

The Rezūm System (NxThera, Inc., Maple Grove, MN) received Section 510(k) approval from the FDA in August 2015.

The FDA indications for Rezūm System are:

- Men \geq 50 years of age;
- Prostate volume \geq 30 cm³ and \leq 80 cm³;
- Intended to relieve symptoms, obstructions;
- Reduce prostate tissue associated with BPH;
- Treatment of prostate with hyperplasia of the central zone and/or median lobe.

In 2013, the FDA granted a de novo classification clearance for the UroLift System.

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 13 of 21

In January 2017, the FDA granted Section 510(k) clearance for the UroLift System (UL400 and UL500) for the treatment of symptoms due to urinary outflow obstruction secondary to BPH, including lateral and median lobe hyperplasia, in men 45 years of age or older.

In December 2019, the FDA modified the list of contraindications for the UroLift System (UL400) from prostate volume greater than 80 cc to prostate volume greater than 100 cc. The FDA indicated that its decision was based on clinical review of both sponsored and independent clinical studies that included men with prostate volumes greater than 80 cc, which showed that the symptom response, quality of life, uroflowmetry, adverse events, and catheterization rates were equivalent to the outcomes of patients with prostate volumes less than 80cc.

In June 2020, the FDA granted section 510(k) clearance for the UroLift Advanced Tissue Control (ATC) System. A modification of the UroLift UL400 System, where the primary difference is the addition of a wing component on the distal tip of the UL400 which provides a larger footprint. This design feature is intended to provide better mobilization of tissue when performing the UroLift System procedure.

In July 2020, the FDA granted Section 510(k) clearance for the UroLift 2 System (UL2) for the treatment of urinary outflow obstruction secondary to BPH, including lateral and median lobe hyperplasia in men 45 years of age and older. The UL2 system is substantially equivalent to previous cleared generation devices. Minor device modifications have been made to the UL2 Delivery System (Delivery handle and implant cartridge) that do not affect the overall safety and effectiveness of the UroLift procedure. No modifications have been made to the UroLift Implant.

In 2020, the FDA expanded coverage of the UroLift system to treat prostates between 80-100 ccs.

The FDA Contraindications for the UroLift System are:

- Prostate volume of > 100 cc;
- Urinary tract infection (UTI);
- Urethra conditions that may prevent insertion of delivery system into bladder;
- Urinary incontinence due to incompetent sphincter;
- Current gross hematuria.

Optilume was FDA approved in 2021 for the treatment of men with urethral strictures.

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)**Policy Number: 7.01.104****Page: 14 of 21**

Code	Description
0714T (E/I)	Transperineal laser ablation of benign prostatic hyperplasia, including imaging guidance; prostate volume less than 50 mL
0867T (E/I)	Transperineal laser ablation of benign prostatic hyperplasia, including imaging guidance; prostate volume greater or equal to 50 mL
37242	Vascular embolization or occlusion, inclusive of all radiological supervision and interpretation, intraprocedural roadmapping, and imaging guidance necessary to complete the intervention; arterial, other than hemorrhage or tumor (eg, congenital or acquired arterial malformations, arteriovenous malformations, arteriovenous fistulas, aneurysms, pseudoaneurysms) (e.g., PAE)
37243	Vascular embolization or occlusion, inclusive of all radiological supervision and interpretation, intraprocedural roadmapping, and imaging guidance necessary to complete the intervention; for tumors, organ ischemia, or infarction (e.g., PAE)
52284 (E/I)	Cystourethroscopy, with mechanical urethral dilation and urethral therapeutic drug delivery by drug-coated balloon catheter for urethral stricture or stenosis, male, including fluoroscopy, when performed (e.g., Optilume)
52441	Cystourethroscopy, with insertion of permanent adjustable transprostatic implant; single implant (e.g., PUL)
52442	Cystourethroscopy, with insertion of permanent adjustable transprostatic implant; each additional permanent adjustable transprostatic implant (List separately in addition to code for primary procedure) (e.g., PUL)
52443 (E/I)	Cystourethroscopy with initial transurethral anterior prostate commissurotomy with a nondrug-coated balloon catheter followed by therapeutic drug delivery into the prostate by a drug-coated balloon catheter, including transrectal ultrasound and fluoroscopy, when performed (Effective 01/01/26) (Replacing code 0619T)
0619T Termed 12/31/25	Cystourethroscopy with transurethral anterior prostate commissurotomy and drug delivery, including transrectal ultrasound and fluoroscopy, when performed

Medical Policy: Minimally Invasive Treatments for Benign Prostatic Hyperplasia (BPH)

Policy Number: 7.01.104

Page: 15 of 21

Code	Description
53854	Transurethral destruction of prostate tissue; by radiofrequency generated water vapor thermotherapy (e.g., Rezum)
53865 (E/I)	Cystourethroscopy with insertion of temporary device for ischemic remodeling (ie, pressure necrosis) of bladder neck and prostate (effective 01/01/2025) (e.g., iTIND)
53866 (E/I)	Catheterization with removal of temporary device for ischemic remodeling (ie, pressure necrosis) of bladder neck and prostate (effective 01/01/2025) (e.g., iTIND)
52597 Effective 01/01/26	Transurethral robotic-assisted waterjet resection of prostate, including intraoperative planning, ultrasound guidance, control of postoperative bleeding, complete, including vasectomy, meatotomy, cystourethroscopy, urethral calibration and/or dilation, and internal urethrotomy, when performed (Effective 01/01/26) (Replacing code 0421T)
0421T Termed 12/31/25	Transurethral waterjet ablation of prostate, including control of post-operative bleeding, including ultrasound guidance, complete (vasectomy, meatotomy, cystourethroscopy, urethral calibration and/or dilation, and internal urethrotomy are included when performed)

Prostatic urethral lift is not addressed in National or Regional Medicare coverage determinations or policies.

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product (including Medicare HMO-Dual Special Needs Program (DSNP) product) covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.
- If a Medicare HMO-Dual Special Needs Program (DSNP) product DOES NOT cover a specific service, please refer to the Medicaid Product coverage line.
